Introduction.

Reading the book [Delta Lake, The Definitive Guide.]

I got to know first hand that Delta lake also supports write operation. Like Delta can support concurrent read & write, becoming a total Scalable transaction consistency monster.

**

I was under the wrong assumption that only reads are supported,

I used to think

But then I ran a trivial query on Argo's data studio a bit updating a row in delta, and it did that.

So now I see delta differently. Basically

delta is ACID but at scale.

While reading through the introduction, I came across the word delta protocol.

Delta Protocol $\rightarrow$ it is a specification that defines how clients interact with Delta Lake tables in a consistent transactional manner.

Key features.

- * ACID
- * incremental-processing
- * Schema-enforcement

* time-travel
* data-versioning
* data-skipping

$\rightarrow$ I am excited to learn all these
